## Declaration of Authorship

I, Mykola MORHUNENKO, declare that this thesis titled, “Multi-camera visual collision avoidance for micro aerial vehicles” and the work presented in it are my own. I confirm that:

- This work was done wholly or mainly while in candidature for a research degree at this University.
- Where any part of this thesis has previously been submitted for a degree or any other qualification at this University or any other institution, this has been clearly stated.
- Where I have consulted the published work of others, this is always clearly attributed.
- Where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work.
- I have acknowledged all main sources of help.
- Where the thesis is based on work done by myself jointly with others, I have made clear exactly what was done by others and what I have contributed myself.

**Multi-camera visual collision avoidance for micro aerial vehicles**

by Mykola MORHUNENKO

## *Abstract*

We live in a twenty first century - time of extremely fast developing of all electronic devices. Each month we see some brake-through in such directions as microchips modeling, flying vehicles developing, quantum computing and space exploration, bioengineering and medicine.

in the thesis I would like to focus on micro aerial vehicles as one of the most perspective development directions and interesting personally for me. During my internship in the MRS Group I was working a lot with computer vision, and I see it as quite promising direction.

Specifically, visual collision avoidance is one of the relevant topics that is being actively researched nowadays. Drones with this feature becomes more preferable - they are safer, can last longer and easier to control. Visual collision avoidance is much less expensive than Lidars.

## *Acknowledgements*

I would like to thank my supervisor Ing. Matouš Vrba and all CTU MRS Group for the opportunity to have an internship there for last one and a half year, all of them was kind, they helped me a lot with advice's and sharing their experience, CTU FEE for interesting and useful for this thesis courses. I want to admire that nothing my study will not take place without my small family - Ukrainian Catholic University, especially Applied Science Faculty, all teachers and deanery for saving all students from all the worst sides of Ukrainian education system and providing only the best quality education without corruption and plagiarism.

Especially I want to thank all defenders of my Motherland, The Armed Forces of Ukraine, who protect the whole Europe during the russo-Ukraian war at the cost of their own lives to make it possible for all of us to live in peace and for me to write this thesis.

Finally, I would like to thank my family who supported me during whole my life, my mother Svitlana and my father Roman.

## Chapter 1

# Introduction

Micro unmanned aerial vehicles (MAVs) recently saw a rise in usage across various fields. Drones are already wide used in cinematography<sup>1</sup> and advertising<sup>2</sup>, In Ukraine they are very helpful in farming (to apply pesticides to fields)<sup>3</sup>. City emergency departments use UAVs - firefighters can use them to see and evaluate the situation from the sky, localise the source of fire and deal with that<sup>4</sup>, sometimes it even can have some fire-extinguishing capsules as projectiles<sup>5</sup>. They are also quite popular in military industry.

There is no precise definition of MAV; modern MAVs can even be as small as 5 centimetres, but more generally - it is an Unmanned aerial vehicles (UAVs) with some size and weight limitations.

The inspiration for this project was taken from DJI obstacle avoidance technology introduced with the release of the DJI Mavic 3 drone<sup>6</sup> on fifth November 2021. Despite the fact that the idea is old, neither DJI nor MRS nor other research groups have a well-developed visual obstacle avoidance system, the best for now can be Skydio obstacle avoidance system, so this direction is very perspective for researchers. Many drones available for sale are costly, and even a well-trained pilot is afraid of crashing. At the same time, autonomous drones are more predictable than a human pilot, behave according to algorithms and can react much faster, but only if they have a well-designed system running on board, so obstacle avoidance for autonomous MAVs will be both more challenging and more critical in future trends.

While obstacle avoidance considers static objects, collision avoidance is related to averting crashing with moving objects like other MAVs, cars or people. It is a complicated task but more relevant to multi-robot systems, because during interactions between robots they should not brake each other.

There are several obstacle avoidance sensors used by various MAVs: stereo vision [4], depth cameras (as Intel RealSense), monocular vision [1], lidar (2d or 3d) [2], sonar (ultrasonic), time of flight sensors, also combinations of them can be used. In [3] the sensor fusion of ultrasonic and infrared sensors is presented.

Each of them has its pros and cons. 3d lidars are extremely expensive but the most efficient for today; 2d lidars are used for small ground vehicles, but not suitable for most tasks for MAVs (because a car can be modelled as a 2 DoF system, while MAV always has 6 DoF), depth cameras are relatively expensive too, ultrasonic and infrared sensors both have distance limits and other minor issues. Overall, stereo vision is the most promising approach for the nearest future.

## 1.1 Related Works

The goal of this thesis is to implement an obstacle avoidance system, and expand it to collision avoidance system for autonomous MAVs driven by a Robotic operating system (ROS) using the MRS UAV system<sup>7</sup>.

Firstly it is necessary to calibrate a stereo pair, then implement a structure from motion algorithm for each camera and find moving objects using the fact of overlapping sones for each camera.
